

A South American automotive financing company

Tightens data security and automates audit reporting across mainframe and distributed environments

Overview

The need

The bank's internally developed tool to control database access and secure information did not provide the comprehensive capabilities needed to meet audit and compliance requirements.

The solution

Working with IBM Business Partner LeadComm, the bank implemented IBM® InfoSphere® Guardium® software to more effectively prevent unauthorized activities and monitor database changes across its distributed and mainframe environments.

The benefit

Helped tighten database security to better protect client data; reduced compliance reporting times by 99 percent; decreased staff needed to manage database monitoring by 75 percent

Two years ago, IT staff at this South American automotive financing company conducted a review of the bank's IT security and governance programs. This effort was part of the bank's ongoing work to protect client information.

At the outset, a key focus area was database security. The bank had used an internally developed solution to control authorized access and secure information in application databases. However, this solution was decentralized and had to be updated to support timely audit reporting and compliance requirements. The challenge was to find a technology solution that would secure and safeguard the company's critical financial and transactional information and provide a high level of granularity for defining security policies for all users.

The IT organization wanted to see exactly who accessed what information. For example, at times, developers need to access the bank's production database to investigate application issues. When this type of temporary access is granted, it is critical that these privileged users are not making unauthorized changes to the data.

The bank needed a solution that would provide these capabilities for all application databases in both the distributed and mainframe environments.

With the new solution, the IT team can continuously monitor access and automate compliance controls across its distributed and mainframe application databases.

Monitoring access across a heterogeneous environment

The IT team launched a Proof-of-Concept evaluation to assess off-the-shelf database monitoring solutions. At first, the evaluation criteria targeted separate solutions to support the bank's databases in the distributed and IBM z/OS® mainframe environments. However, once the team learned about IBM InfoSphere Guardium Database Activity Monitor software, the criteria changed as staff members realized that they could have one solution for application databases in both their mainframe and distributed environments.

IBM Business Partner LeadComm assisted the team with the implementation.

Gaining greater visibility into database transactions

With the new solution, the organization can continuously monitor access and automate compliance controls across its distributed and mainframe application databases. Using the platform, IT staff can easily:

- Define database security and access policies and track these activities at a detailed level of granularity
- Locate and classify sensitive information in the organization's application databases
- Evaluate the vulnerabilities and imperfections of database configurations
- Confirm that configurations are not modified after they are applied
- Automate compliance and reporting processes, including report distribution

This increased visibility is helping the organization confirm that client data is protected. Today, just one IT staff member can manage control across all databases. The organization estimates that it would have probably needed four people to do this work without InfoSphere Guardium software, taking IT staff away from other critical projects.

Solution components

Software

- IBM® InfoSphere® Guardium® Database Activity Monitor
- IBM InfoSphere Guardium Database Activity Monitor for z/OS®

IBM Business Partner

- LeadComm

In the past, a database administrator (DBA) had to manually check database log files and then create the compliance reports—a process that used to take tens of hours. This work can now be completed in minutes.

Additionally, audit and compliance reporting processes are automated and can now be completed 99 percent faster—a huge time saver for IT staff. For example, in the past, a database administrator (DBA) had to manually check database log files and then create the compliance reports—a process that used to take tens of hours. This work can now be completed in minutes.

Audit reports delivered to external regulatory entities verify that the bank has the proper controls and security measures in place.

Alerting business users to important database changes

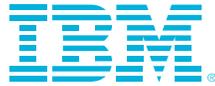

The project began as many IT projects do. Its focus was on solving a specific business issue—in this case monitoring database activity to prevent unauthorized access to data. However, the team quickly realized that it could use the new solution to deliver greater oversight to business managers.

For example, certain data, such as interest rates, can be changed only at certain times of the year. Previously, IT personnel could know if a user was allowed to make a change, but had no way of knowing when the change was made. Now, the solution alerts business managers, for example, when interest rates are changed in the system. They can also confirm that only authorized users made the changes and that the changes were made within the permitted timeframe.

Statement of Good Security Practices: IT system security involves protecting systems and information through prevention, detection and response to improper access from within and outside your enterprise. Improper access can result in information being altered, destroyed or misappropriated or can result in damage to or misuse of your systems, including to attack others. No IT system or product should be considered completely secure and no single product or security measure can be completely effective in preventing improper access. IBM systems and products are designed to be part of a comprehensive security approach, which will necessarily involve additional operational procedures, and may require other systems, products or services to be most effective. IBM does not warrant that systems and products are immune from the malicious or illegal conduct of any party.
